Abstract

Machine translation (MT) systems are not able to always produce translations of human-level quality. As a practical means of such MT systems, we investigated the potential of pre-editing strategy, by collecting actual pre-edit instances using a human-in-the-loop protocol. In our study, targeting Japanese-to-English translation on four different datasets and using an off-the-shelf MT system, we collected a total of 12,287 pre-edit instances for 400 source sentences and showed promising results; more than 85% of source sentences turned out to be accurately translated by the MT system. We also found that the pre-edited Japanese source sentences were better translated into Chinese and Korean, confirming the usefulness of pre-editing strategy in a multilingual setting. Through decomposing the collected pre-edit instances, we built a typology of primitive edit operations comprising 53 types, which unveils the subjects for further research.

1 Introduction

Given the improved quality of machine translation (MT) and the increased demand for rapid delivery of translations, a number of off-the-shelf MT systems have become available. However, none of them can guarantee that their raw outputs are always of sufficient quality. When we consider embedding such MT systems in computer-aided translation (CAT) settings, it is indispensable to explore practical means to obtain high-quality translations without configuring the MT systems.

One option to make better use of such MT systems is to edit source text (ST) so that it is amenable to the targeted MT system, i.e., pre-editing. As demonstrated in the literature, pre-editing ST leads to improved MT quality (Bernth and Gdaniec, 2001; Miyata et al., 2015) and reduced post-editing effort (Pym, 1988; O’Brien and Roturier, 2007; Aikawa et al., 2007). Controlling ST is particularly effective in multilingual settings (Ó Broin, 2009).

Several studies have examined human-in-the-loop protocols that include pre-editing ST in order to improve MT quality. Uchimoto et al. (2006) have used back translation as a means to spot non-machine-translatable spans in ST, which are subsequently served to humans to be edited. Resnik et al. (2010) have taken advantage of monolingual human knowledge of the target language to identify spans of ST that are likely to cause translation errors. Mirkin et al. (2013) have devised an interactive tool for monolingual authors. It suggests appropriate alternatives along with confidence scores for MT outputs.

In this paper, we investigate the capability of the pre-editing strategy and provide an overview of possible edit operations used for pre-editing. First, we empirically demonstrate the potential usefulness of the pre-editing strategy, i.e., how often STs turn out to be accurately translated by a targeted MT system. To this end, we designed a human-in-the-loop protocol, in which human editors incrementally edit given STs (Section 2), and experimented with Japanese-to-English translation tasks on four different datasets (Section 3). Using the original and the best-edited STs, we also
investigated the usefulness of the pre-edited STs in translating Japanese STs into Chinese and Korean (Section 4). To give an overall picture of pre-editing, we built a typology of edit operations upon actual pre-edit instances, i.e., pairs of STs before/after minimal pre-editing, collected through the above protocol followed by manual decomposition (Section 5). The typology can act as a guidepost to determine useful operations, such as those having the largest impact on the MT quality and those that are easy to automate.

2 Protocol for Collecting Pre-editing Instances

As in Miyata et al. (2015), we ask human editors to incrementally edit STs relying on their introspection, so that improved MT quality is achieved. Miyata et al. (2015) collected only the final versions of edited STs and directly compared them with the originals. In contrast, we aim to observe the trials and errors of editors and to achieve translations of satisfactory quality as much as possible. To that end, we developed a Web-based platform, shown in Figure 1, with the following two features.

- We record ST after every minimal edit is performed in order to capture the detailed process of pre-editing.
- We allow editors to resume editing from any given past version of ST in order to facilitate their trial and error.

Editors are asked to follow the iterative procedure given below for each original ST. We refer to the set of collected versions of STs for the same original ST as a unit.

**Step 1.** Assess the MT output for the present ST according to the 5-point scale criterion in Table 1. Go to Step 4, if it has satisfactory quality; otherwise, go to Step 2.

**Step 2.** Select one version of ST to be edited, from the past versions of STs, referring to the corresponding MT outputs, and go to Step 3; if none is likely to achieve satisfactory quality even if edited, go to Step 4.

**Step 3.** Minimally edit the selected version of ST, while keeping the meaning of the ST, referring to the MT output for it, so that the MT system would be able to generate a better translation. When the edited ST is submitted, its MT output is automatically generated and registered together. Go back to Step 1.

**Step 4.** Choose one version of ST that achieves the best MT quality among all the versions registered in the unit (called the Best ST), and terminate the procedure for this ST.

To observe fine-grained edit operations, we instructed editors to make edits primitive as much as possible in Step 3, showing some examples. Table 2 shows an example; a phrase reordering for sentence (a) makes sentence (b), and a passiviza-

Figure 2: Tree representation of versions of STs shown in Figure 1.

In three domains: hospital conversation\(^2\) (hosp), living information provided by municipalities\(^3\) (muni), and two types of news articles, Japanese-origin ones from BCCWJ\(^4\) (bccwj) and English-origin ones from Reuters\(^5\) (reuters). While hosp is spoken, the others are written; sentence length is markedly diverse (see also Table 3). These domains are so different from each other that we expect that the applicability of our proposed protocol can be evaluated from diverse points of view. For each dataset, we randomly sampled 100 Japanese sentences and used them as original STs.

As the off-the-shelf MT system, we used TexTra,\(^6\) a freely-available, state-of-the-art phrase-based statistical MT system, through its REST API. We assigned the pre-editing task to one native Japanese speaker who has a good command of English and ample experience in evaluating the quality of various types of MT systems according to the criterion in Table 1, while she has no prior knowledge of TexTra.

As a result, 12,687 versions of STs and thus 12,287 pre-edit instances were collected; see Table 3 for statistics. As shown in the rightmost column, more than 85% of the STs were ended with MT outputs of satisfactory quality. This demonstrates the high potential of the MT system when proper human intervention is incorporated. In general, the longer the original ST was, the more edit operations were required to attain satisfactory quality. Table 4 shows an example of the Best ST of a unit in reuters, which was obtained after 25 consecutive edits in the best path and the MT output of which met satisfactory quality.

It should also be noted that 27 out of 400 units did not attain satisfactory quality in our human-in-the-loop protocol. Among these “Give up” cases, we identified that mis-translation of proper nouns and incorrect lexical choices were the most difficult types of MT errors to rectify. For example, the Best ST in Table 5 contains expressions for dates, “4 日,” “5 日,” and “6 日,” proper translations of which are “4th,” “5th,” and “6th,” respectively. The MT system specified “June” improperly. This error stems from the wrong phrase alignment in the statistical model. These types of errors should be addressed during training the models and/or post-editing, rather than pre-editing. Our protocol enables us to identify MT errors that are difficult to amend only by the pre-editing strategy. This will eventually help us streamline the overall translation workflow using off-the-shelf MT systems.

4 Machine Translatability for Different Languages

We examined the effectiveness of the pre-editing strategy in a multilingual translation setting, i.e., whether an ST, edited so that it is better translated into one target language, can also be better translated into other languages. First, all the original and the Best STs in the four datasets (800 sentences in total) were translated into Chinese and Korean using the corresponding models of TexTra. Then, for each set of Chinese and Korean translations, one human evaluator was asked to assess the MT quality using the 5-point scale in Table 1. As shown in Table 6, the MT quality for the Best STs was, on average, higher than that for the original STs for all the datasets, indicating that edit operations that improved English-translatability of Japanese STs are portable to Chinese- and Korean-translatability to a certain degree. For both languages, the MT quality for the Best STs in hosp and bccwj well surpassed that for the original STs, while there were no significant improvements in muni and reuters. Further scrutiny into the language dependency of machine-translatability is important to justify the pre-editing approach to other target languages and domains.

5 Typology of Edit Operations

We analyzed the diversity of edit operations exhibited during our pre-editing exercise. As mentioned in Section 2, it is likely that the best path contains edit operations effective in improving MT quality. We therefore focused on pre-edit instances in the
Once (both mean operations such as replacing “C01 (Alternative lexical choice)”, including edit of syntactic alternation. punctuation and word reordering, to various types of edit operations in our collection, ranging from in each dataset. We observed an extended variety of pre-edit instances, with their frequency 53 types of edit operations that cover all of the clues. Table 8 shows the resulting typology with surface-level differences of each pair of STs as

We then manually created a typology of edit operations, by categorizing each instance, regarding erations, by from 1.40 to 1.95 times, resulting a total of 979 instances of primitive edit operations. This type of edit operation has not been covered by existing controlled language rule sets in Japanese, such as (Ogura et al., 2010; Hartley et al., 2012; Miyata et al., 2015), nor even by a comprehensive typology of paraphrases.7 It is worth exploring to what extent these types of edit operations are effective in improving MT quality.

Last but not least, let us describe a less frequent type of edit operations, i.e., S13 (Head-switching of verb phrase):

This type of edit operation has not been covered by existing controlled language rule sets in Japanese, such as (Ogura et al., 2010; Hartley et al., 2012; Miyata et al., 2015), nor even by a comprehensive typology of paraphrases.7 It is worth exploring to what extent these types of edit operations are effective in improving MT quality.

6 Conclusion and Future Work

In this paper, we have presented our human-in-the-loop protocol for collecting pre-edit instances. Using this protocol, we collected 12,287 pre-edit instances for four different datasets, demonstrating that most of the source sentences can be edited into machine-translatable ones. Human evaluation revealed that, for some datasets, English-translatable Japanese STs significantly improved the quality of translations into Chinese and Korean. We also built a typology comprising a wide range of edit operations, and found that alternating lexical choice was the most frequent one taken by our editor.

Based on this study, we plan to develop an automatic pre-editor. One approach to this is controlled language formulation by assessing the effectiveness of each type of edit operation (Bernth and Gdaniec, 2001; Miyata et al., 2015). Another is to build a statistical model. It is worth investigating data-driven methods based on our collection of pre-edit instances, although this data do not guar-

Table 7: The number of decomposed pre-editing instances in the best path of 10 sampled units.

Table: Best path of 10 randomly sampled units for each of the four datasets. First, we decomposed each of the sampled 568 instances into a sequence of primitive edit operations, because our editor might not strictly seek the primitiveness. Indeed, as shown in Table 7, this process increased the number of instances by from 1.40 to 1.95 times, resulting a total of 979 instances of primitive edit operations. We then manually created a typology of edit operations, by categorizing each instance, regarding surface-level differences of each pair of STs as clues. Table 8 shows the resulting typology with 53 types of edit operations that cover all of the analyzed pre-edit instances, with their frequency in each dataset. We observed an extended variety of edit operations in our collection, ranging from ones at surface-level, such as insertion/deletion of punctuation and word reordering, to various types of syntactic alternation.

The most frequent type across the datasets was C01 (Alternative lexical choice), including edit operations such as replacing “一度” with “一回” (both mean once), and “習得する” (acquire) with “学ぶ” (learn). This type of edit operations would be automated by constructing lexical resources tailored to particular MT systems. We also identified several frequent types of edit operations that are likely to be effective for improving MT quality. For example, S05 (Phrase reordering) and S07 (Insertion/deletion of punctuation) can help MT systems parse the input sentences correctly, which subsequently leads to better MT outputs.

Some types of edit operations were observed only in specific domains. For example, we observed S15 (Use/disuse of clause-ending noun) and S20 (Use/disuse of nominal/verbal suffix) only in the news domain (bccwj and reuters). Both types reflect the fact that the elliptic expressions often used in news articles could degrade the MT quality. Our method is also useful to unveil these kinds of domain-specific issues.

Last but not least, let us describe a less frequent type of edit operations, i.e., S13 (Head-switching of verb phrase):

[before] 懸念を強め (strengthen anxiety)
[after] 強い懸念を抱き (have strong anxiety)

This type of edit operation has not been covered by existing controlled language rule sets in Japanese, such as (Ogura et al., 2010; Hartley et al., 2012; Miyata et al., 2015), nor even by a comprehensive typology of paraphrases.7 It is worth exploring to what extent these types of edit operations are effective in improving MT quality.

6 Conclusion and Future Work

In this paper, we have presented our human-in-the-loop protocol for collecting pre-edit instances. Using this protocol, we collected 12,287 pre-edit instances for four different datasets, demonstrating that most of the source sentences can be edited into machine-translatable ones. Human evaluation revealed that, for some datasets, English-translatable Japanese STs significantly improved the quality of translations into Chinese and Korean. We also built a typology comprising a wide range of edit operations, and found that alternating lexical choice was the most frequent one taken by our editor.

Based on this study, we plan to develop an automatic pre-editor. One approach to this is controlled language formulation by assessing the effectiveness of each type of edit operation (Bernth and Gdaniec, 2001; Miyata et al., 2015). Another is to build a statistical model. It is worth investigating data-driven methods based on our collection of pre-edit instances, although this data do not guar-
antee to improve MT quality as directly addressed by post-editing (Simard et al., 2007).

Acknowledgments

We are deeply grateful to the anonymous reviewers for their valuable comments on the earlier version of this paper. This work was partly supported by JSPS KAKENHI Grant Numbers 25730139 and 25240051.
