

# **Introduction to Machine Learning**

Jindřich Libovický (reusing materials by Milan Straka)

**iii** October 03, 2023

Charles University in Prague Faculty of Mathematics and Physics Institute of Formal and Applied Linguistics

unless otherwise stated

### **Course Objectives: What you will learn**

Ú F<sub>A</sub>L

After this course you should...

- Be able to reason about task/problems suitable for ML
  - $\circ~$  Know when to use classification, regression and clustering
  - $^{\circ}\,$  Be able to choose from this method Linear and Logistic Regression, Multilayer Perceptron, Nearest Neighbors, Naive Bayes, Gradient Boosted Decision Trees, k-means clustering
- Think about learning as (mostly probabilistic) optimization on training data
  O Know how the ML methods learn including theoretical explanation
- Know how to properly evaluate ML
  - $\circ$  Think about generalization (and avoiding overfitting)
  - $^{\circ}~$  Be able to choose a suitable evaluation metric
  - $\circ~$  Responsibly decide what model is better
- Be able to implement ML algorithms on a conceptual level
- Be able to use Scikit-learn to solve ML problems in Python

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data L

- Data Science How to (ethically, legally, effeciently, etc.) get data and how to **clean** data.
- More advanced neural networks (and how ChatGPT works) this is covered in <u>NPFL114</u>
- How to apply ML in your specific field / your business

### Organization

### **Course Website:** <u>https://ufal.mff.cuni.cz/courses/npfl129</u>

• Slides, recordings, assignments, exam questions

**Course Repository:** <u>https://github.com/ufal/npfl129</u>

• Templates for the assignments, slide sources.

## Piazza

• Piazza will be used as a communication platform.

You can post questions or notes,

- $\circ~$  privately to the instructors,
- **publicly** to everyone (signed or anonymously).
  - Other students can answer these too, which allows you to get faster response.
  - However, do not include even parts of your source code in public questions.
- Please use Piazza for all communication with the instructors.
- You will get the invite link after the first lecture.

NPFL129, Lecture 1

Organization Machine Learning

### ReCodEx

### https://recodex.mff.cuni.cz

- The assignments will be evaluated automatically in ReCodEx.
- If you have a MFF SIS account, you should be able to create an account using your CAS credentials and should automatically see the right group.
- Otherwise, there will be **instructions** on **Piazza** how to get ReCodEx account (generally you will need to send me a message with several pieces of information and I will send it to ReCodEx administrators in batches).

### **Course Requirements**

#### Ú FÂL

## Practicals

- There will be about 2-3 assignments a week, each with a 2-week deadline.
  There is also another week-long second deadline, but for fewer points.
- After solving the assignment, you get non-bonus points, and sometimes also bonus points.
- To pass the **practicals**, you need to get 70 non-bonus points. There will be assignments for at least 105 non-bonus points.
- If you get **more than 70 points** (be it bonus or non-bonus), they will be *transferred to the exam* (but at most 40 points are transferred).

### Lecture

You need to pass a written exam.

- All questions are publicly listed on the course website.
- There are questions for 100 points in every exam, plus at most 40 surplus points from the practicals and plus at most 10 surplus points for **community work** (improving slides, ...).
- You need 60/75/90 points to pass with grade 3/2/1.

After this lecture you should be able to

- Explain to an non-expert what machine learning is
- Explain the difference between classification and regression
- Implement a simple linear-algebra-based algorithm for training linear regression

NPFL129, Lecture 1

g Basic Setting

Input Data

### Machine Learning

A possible definition of learning from Mitchell (1997):

A computer program is said to learn from **experience E** with respect to some class of tasks T and performance measure P, if its performance at tasks in T, as measured by P, improves with experience E.

Task T

 $\circ$  *classification*: assigning one of k categories to a given input

- $\circ$  regression: producing a number  $x \in \mathbb{R}$  for a given input
- structured prediction, denoising, density estimation, ...
- Measure P
  - accuracy, error rate, F-score, ...
- Experience E
  - supervised: usually a dataset with desired outcomes (*labels* or *targets*)
  - *unsupervised*: usually data without any annotation (raw text, raw images, ...)
  - reinforcement learning, semi-supervised learning, ...

### Programming

- We can **formally describe** a problem with clear concepts
- Program = unambiguous set of **instructions** that handles the concepts

*Example - e-shop:* Concepts: goods, store, customer, order, ... Simple algorithms: place an order, send an order, ...

### **Machine Learning**

- We have **data** and a **measure** how our problem is solved
- Typically, we do not know how to code that solves the problem

*Example - machine translation* there is not set of formal instruction how to translate, there is a lot of data

### **Supervised Machine Learning**

Linear Regression Summary

12/29

### **Basic Machine Learning Settings**

Assume input of  $oldsymbol{x} \in \mathbb{R}^D$ . The two basic ML tasks are:

- 1. **Regression**: The goal is to predict a real-valued target variable  $t \in \mathbb{R}$  for given  $\boldsymbol{x}$ .
- 2. Classification: Assuming a fixed set of K labels, the goal is to choose a corresponding label/class for given  $\boldsymbol{x}$ .
  - $\circ~$  We can predict the class only.
  - $\circ~$  We can predict the whole distribution of all classes probabilities.

We usually have a training set:

- Consists of examples of  $(\boldsymbol{x},t)$
- Probabilistic interpretation: Generated independently from a data-generating distribution

NPFL129, Lecture 1

Basic Setting

Input Data

- **Optimization** = match the training set as well as possible
- ML's goals is **generalization** = match **previously unseen data** as well as possible

## ÷∐?

We typically estimate it using a **test set** of examples independent of the training set. (in probabilistic interpretation generated by the same data-generating distribution)

NPFL129, Lecture 1

Basic Setting

### Notation

- a, a, A, A: scalar (integer or real), vector, matrix, tensor
  - $^{\circ}~$  all vectors are always  ${\color{black} column}$  vectors
  - $^{\circ}$  transposition changes a column vector into a row vector, so  $oldsymbol{a}^T$  is a row vector
  - $^{\circ}$  we denote the **dot (scalar) product** of the vectors  $\boldsymbol{a}$  and  $\boldsymbol{b}$  using  $\boldsymbol{a}^T \boldsymbol{b}$ 
    - we understand it as matrix multiplication

$$^\circ$$
 the  $\|m{a}\|_2$  or just  $\|m{a}\|$  is the Euclidean (or  $L^2$ ) norm  $lacksquare$   $\|m{a}\|_2=\sqrt{\sum_i a_i^2}$ 

- a, **a**, **A**: scalar, vector, matrix random variable
- A: set;  ${\mathbb R}$  is the set of real numbers,  ${\mathbb C}$  is the set of complex numbers
- $\frac{df}{dx}$ : derivative of f with respect to x
- $\frac{\partial f}{\partial x}$ : partial derivative of f with respect to x
- $\nabla_{\boldsymbol{x}} f(\boldsymbol{x})$ : gradient of f with respect to  $\boldsymbol{x}$ , i.e.,  $\left(\frac{\partial f(\boldsymbol{x})}{\partial x_1}, \frac{\partial f(\boldsymbol{x})}{\partial x_2}, \dots, \frac{\partial f(\boldsymbol{x})}{\partial x_n}\right)$

### **Example Dataset**

Assume we have the following data, generated from an underlying curve by adding a small amount of noise.

NPFL129, Lecture 1

Basic Setting

### Input Data

Usually, ML algorithms are trained using the train set  $X \in \mathbb{R}^{N \times D}$ : a collection of N instances, each represented by D real numbers.

In supervised learning, we also have a target  $m{t}$  for every instance,

- a real number for regression,  $oldsymbol{t} \in \mathbb{R}^N$ ;
- a class for classification,  $oldsymbol{t} \in \{0,1,\ldots,K-1\}^N$  .

The input to ML learning algorithms is frequently preprocessed, i.e., the algorithms do not always work directly on the input X, but on some modification of it. These are called **features**.

In some literature, processed inputs are called a **design matrix**  $\Phi \in \mathbb{R}^{N \times M}$ , we will denote everything as X.

NPFL129, Lecture 1

Basic Setting

Input Data

### **Linear Regression**

Given an input value  $\boldsymbol{x} \in \mathbb{R}^D$ , one of the simplest models to predict a target real value is **linear regression**:

$$y(oldsymbol{x};oldsymbol{w},b) = x_1w_1 + x_2w_2 + \ldots + x_Dw_D + b = \sum_{i=1}^D x_iw_i + b = oldsymbol{x}^Toldsymbol{w} + b.$$

The  $\boldsymbol{w}$  are usually called *weights* and  $\boldsymbol{b}$  is called *bias*.

Sometimes it is convenient not to deal with the bias separately. Instead, we might enlarge the input vector  $\boldsymbol{x}$  by padding a value 1, and consider only  $\boldsymbol{x}^T \boldsymbol{w}$ , the bias is encoded by the last weight. Therefore, "weights" often both weights and biases.

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data

### Separate Bias vs. Padding $\boldsymbol{X}$ with Ones

Using an explicit bias term in the form of  $y(x) = \boldsymbol{x}^T \boldsymbol{w} + b$ .

$$egin{bmatrix} x_{11} & x_{12} \ x_{21} & x_{22} \ dots \ x_{n1} & x_{n2} \end{bmatrix} \cdot egin{bmatrix} w_1 \ w_2 \end{bmatrix} + b = egin{bmatrix} w_1 x_{11} + w_2 x_{12} + b \ w_1 x_{21} + w_2 x_{22} + b \ dots \ \$$

With extra 1 padding in  $oldsymbol{X}$  and an additional b weight representing the bias.

$$egin{bmatrix} x_{11} & x_{12} & 1 \ x_{21} & x_{22} & 1 \ dots & dots \ x_{11} & x_{22} & 1 \ dots & dots \ x_{11} & x_{21} + w_2 x_{22} + b \ dots \ x_{11} + w_2 x_{22} + b \ dots \ \ dots \ dot$$

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data

19/29

### **Linear Regression**

We have a dataset of N input values  $oldsymbol{x}_1,\ldots,oldsymbol{x}_N$  and targets  $t_1,\ldots,t_N$ .

Find weight values = minimize an **error function** between the real target values and their predictions.

A popular and simple error function is *mean squared error*:

$$ext{MSE}(oldsymbol{w}) = rac{1}{N}\sum_{i=1}^N ig(y(oldsymbol{x}_i;oldsymbol{w}) - t_iig)^2.$$

Often, sum of squares

$$rac{1}{2}\sum_{i=1}^N ig(y(oldsymbol{x}_i;oldsymbol{w})-t_iig)^2$$

is used instead. Minimizing it is equal to minimizing MSE, but the math comes out nicer.

Summary

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data

### **Linear Regression**

<sup>Ú</sup>F<sub>A</sub>L

Several ways how to minimize the error function – linear regression + sum of squares error have an explicit solution.

Our goal is to minimize:

$$rac{1}{2}\sum_{i}^{N}(oldsymbol{x}_{i}^{T}oldsymbol{w}-t_{i})^{2}.$$

If we denote  $X \in \mathbb{R}^{N \times D}$  the matrix of input values with  $x_i$  on a row i and  $t \in \mathbb{R}^N$  the vector of target values, we can write it as

$$rac{1}{2} \| m{X} m{w} - m{t} \|^2,$$

because

$$\|oldsymbol{X}oldsymbol{w}-oldsymbol{t}\|^2 = \sum_i ig((oldsymbol{X}oldsymbol{w}-oldsymbol{t})_iig)^2 = \sum_iig((oldsymbol{X}oldsymbol{w}-oldsymbol{t}_i)ig)^2 = \sum_iig(oldsymbol{x}_i^Toldsymbol{w}-oldsymbol{t}_i)^2.$$

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data

### Minimization – Unconstrained, Single Real Variable

Assume we have a function and we want to find its minimum.

https://commons.wikimedia.org/wiki/File:Extrema\_example\_original.svg

We usually use the Fermat's theorem (interior extremum theorem):

Let  $f : \mathbb{R} \to \mathbb{R}$  be a function. If it has a minimum (or a maximum) in x and if it has a derivative in x, then  $\frac{\partial f}{\partial x} = 0$ .

### Minimization – Unconstrained, Multiple Real Variables

The previous theorem can be generalized to the multivariate case:

Let  $f:\mathbb{R}^D o\mathbb{R}$  be a function. If it has a minimum or a maximum in  $m{x}=(x_1,x_2,\ldots,x_D)$ and if it has a derivative in  $m{x}$ , then for all i,  $rac{\partial f}{\partial x_i}=0$ . In other words,  $abla_{m{x}}f(m{x})=m{0}$ .

https://commons.wikimedia.org/wiki/File:Partial\_func\_eg.svg

NPFL129, Lecture 1

Organization Machine Learning

Basic Setting

Input Data

Linear Regression

### **Linear Regression**

In order to find a minimum of  $\frac{1}{2} \sum_{i}^{N} (\boldsymbol{x}_{i}^{T} \boldsymbol{w} - t_{i})^{2}$ , we can inspect values where the derivative of the error function is zero, with respect to all weights  $w_{j}$ .

$$rac{\partial}{\partial w_j}rac{1}{2}\sum_i^N(oldsymbol{x}_i^Toldsymbol{w}-t_i)^2 = rac{1}{2}\sum_i^Nig(2(oldsymbol{x}_i^Toldsymbol{w}-t_i)x_{ij}ig) = \sum_i^Nx_{ij}(oldsymbol{x}_i^Toldsymbol{w}-t_i)$$

Therefore, we want for all j that  $\sum_{i}^{N} x_{ij}(\boldsymbol{x}_{i}^{T}\boldsymbol{w} - t_{i}) = 0.$ 

We can rewrite the explicit sum into  $X_{*,j}^T(Xw - t) = 0$ , then write the equations for all j together using matrix notation as  $X^T(Xw - t) = 0$ , and finally, rewrite to

$$\boldsymbol{X}^T \boldsymbol{X} \boldsymbol{w} = \boldsymbol{X}^T \boldsymbol{t}.$$

The matrix  ${m X}^T {m X}$  is of size D imes D. If it is regular, we can compute its inverse and therefore

$$\boldsymbol{w} = (\boldsymbol{X}^T \boldsymbol{X})^{-1} \boldsymbol{X}^T \boldsymbol{t}.$$

### **Linear Regression**

Input: Dataset ( $oldsymbol{X} \in \mathbb{R}^{N imes D}$ ,  $oldsymbol{t} \in \mathbb{R}^N$ ).

**Output**: Weights  $\boldsymbol{w} \in \mathbb{R}^D$  minimizing MSE of linear regression.

• 
$$\boldsymbol{w} \leftarrow (\boldsymbol{X}^T \boldsymbol{X})^{-1} \boldsymbol{X}^T \boldsymbol{t}.$$

The algorithm has complexity  $\mathcal{O}(ND^2)$ , assuming  $N \ge D$ . When the matrix  $\boldsymbol{X}^T \boldsymbol{X}$  is singular, we can solve  $\boldsymbol{X}^T \boldsymbol{X} \boldsymbol{w} = \boldsymbol{X}^T \boldsymbol{t}$  using SVD, which will be demonstrated in the next lecture.

Basic Setting

Input Data

### **Linear Regression Example: Polynomial Features**

We want to predict a  $t \in \mathbb{R}$  for a given  $x \in \mathbb{R}$ . Linear regression with "raw" input vectors x = (x) can only model straight lines.

If we consider input vectors  $oldsymbol{x}=$ M = 0M = 1 $(x^0,x^1,\ldots,x^M)$  for a given  $M\geq 0$  , 0 , the linear regression is able to model polynomials of degree M. The 0 0 prediction is then computed as -1 $w_0x^0+w_1x^1+\ldots+w_Mx^M.$ 0 1 0 xxThe weights are the coefficients of a M = 3M = 9polynomial of degree M. -1-1 0 0 rx26/29NPFL129, Lecture 1 Linear Regression Organization Machine Learning Basic Setting Input Data Summary

### **Linear Regression Example**

To plot the error, the root mean squared error  $RMSE = \sqrt{MSE}$  is frequently used.

The displayed error nicely illustrates two main challenges in machine learning:

- underfitting
- overfitting

After this lecture you should be able to

- Explain to a non-expert what machine learning is
- Explain the difference between classification and regression
- Implement a simple linear-algebra-based algorithm for training linear regression
