December 3, 2018
REINFORCE Algorithm

The REINFORCE algorithm (Williams, 1992) uses directly the policy gradient theorem, maximizing $J(\theta) \defeq \mathbb{E}_{h, \pi} u_\pi(s)$. To compute the gradient

$$\nabla_\theta J(\theta) \propto \sum_{s \in S} \mu(s) \sum_{a \in A} q_\pi(s, a) \nabla_\theta \pi(a | s; \theta),$$

REINFORCE algorithm estimates the $q_\pi(s, a)$ by a single sample.

Modification of Algorithm 13.3 of "Reinforcement Learning: An Introduction, Second Edition".
REINFORCE with Baseline

The returns can be arbitrary – better-than-average and worse-than-average returns cannot be recognized from the absolute value of the return.

Hopefully, we can generalize the policy gradient theorem using a baseline \( b(s) \) to

\[
\nabla_\theta J(\theta) \propto \sum_{s \in S} \mu(s) \sum_{a \in A} (q_\pi(s, a) - b(s)) \nabla_\theta \pi(a|s; \theta).
\]

A good choice for \( b(s) \) is \( v_\pi(s) \), which can be shown to minimize variance of the estimator. Such baseline reminds centering of returns, given that \( v_\pi(s) = \mathbb{E}_{a \sim \pi} q_\pi(s, a) \). Then, better-than-average returns are positive and worse-than-average returns are negative.

The resulting value is also called an *advantage function* \( a_\pi(s, a) \equiv q_\pi(s, a) - v_\pi(s) \).

Of course, the \( v_\pi(s) \) baseline can be only approximated. If neural networks are used to estimate \( \pi(a|s; \theta) \), then some part of the network is usually shared between the policy and value function estimation, which is trained using mean square error of the predicted and observed return.
REINFORCE with Baseline

**REINFORCE with Baseline (episodic), for estimating** \(\pi_\theta \approx \pi_*\)

Input: a differentiable policy parameterization \(\pi(a|s, \theta)\)
Input: a differentiable state-value function parameterization \(\hat{v}(s, w)\)
Algorithm parameters: step sizes \(\alpha^\theta > 0, \alpha^w > 0\)
Initialize policy parameter \(\theta \in \mathbb{R}^{d'}\) and state-value weights \(w \in \mathbb{R}^d\) (e.g., to 0)

Loop forever (for each episode):

- Generate an episode \(S_0, A_0, R_1, \ldots, S_{T-1}, A_{T-1}, R_T\), following \(\pi(\cdot|\cdot, \theta)\)
- Loop for each step of the episode \(t = 0, 1, \ldots, T - 1\):
  \[
  G \leftarrow \sum_{k=t+1}^{T} \gamma^{k-t-1} R_k \\
  \delta \leftarrow G - \hat{v}(S_t, w) \\
  w \leftarrow w + \alpha^w \delta \nabla \hat{v}(S_t, w) \\
  \theta \leftarrow \theta + \alpha^\theta \delta \nabla \ln \pi(A_t|S_t, \theta)
  \]

*Modification of Algorithm 13.4 of "Reinforcement Learning: An Introduction, Second Edition".*
Actor-Critic

It is possible to combine the policy gradient methods and temporal difference methods, creating a family of algorithms usually called *actor-critic* methods.

The idea is straightforward – instead of estimating the episode return using the whole episode rewards, we can use $n$-step temporal difference estimation.

---

**One-step Actor-Critic (episodic), for estimating $\pi_\theta \approx \pi_*$**

Input: a differentiable policy parameterization $\pi(a|s, \theta)$

Input: a differentiable state-value function parameterization $\hat{v}(s, w)$

Parameters: step sizes $\alpha^\theta > 0$, $\alpha^w > 0$

Initialize policy parameter $\theta \in \mathbb{R}^{d'}$ and state-value weights $w \in \mathbb{R}^d$ (e.g., to 0)

Loop forever (for each episode):

  Initialize $S$ (first state of episode)

  Loop while $S$ is not terminal (for each time step):

  $A \sim \pi(\cdot|S, \theta)$

  Take action $A$, observe $S', R$

  $\delta \leftarrow R + \gamma \hat{v}(S', w) - \hat{v}(S, w)$  (if $S'$ is terminal, then $\hat{v}(S', w) = 0$)

  $w \leftarrow w + \alpha^w \delta \nabla \hat{v}(S, w)$

  $\theta \leftarrow \theta + \alpha^\theta \delta \nabla \ln \pi(A|S, \theta)$

  $S \leftarrow S'$

A 2015 paper from Volodymyr Mnih et al., the same group as DQN. The authors propose an asynchronous framework, where multiple workers share one neural network, each training using either an off-line or on-line RL algorithm. They compare 1-step Q-learning, 1-step Sarsa, $n$-step Q-learning and A3C (an *asynchronous advantage actor-critic* method). For A3C, they compare a version with and without LSTM. The authors also introduce *entropy regularization term* $\beta H(\pi(s; \theta))$ to the loss to support exploration and discourage premature convergence.
Asynchronous Methods for Deep RL

Algorithm 1 Asynchronous one-step Q-learning - pseudocode for each actor-learner thread.

//Assume global shared $\theta, \theta^-$, and counter $T = 0$.
Initialize thread step counter $t \leftarrow 0$
Initialize target network weights $\theta^- \leftarrow \theta$
Initialize network gradients $d\theta \leftarrow 0$
Get initial state $s$
repeat
    Take action $a$ with $\epsilon$-greedy policy based on $Q(s, a; \theta)$
    Receive new state $s'$ and reward $r$
    $y = \begin{cases} 
        r & \text{for terminal } s' \\
        r + \gamma \max_{a'} Q(s', a'; \theta^-) & \text{for non-terminal } s'
    \end{cases}$
    Accumulate gradients wrt $\theta$: $d\theta \leftarrow d\theta + \frac{\partial(y-Q(s, a; \theta))}{\partial \theta}$
    $s = s'$
    $T \leftarrow T + 1$ and $t \leftarrow t + 1$
    if $T \mod I_{target} == 0$ then
        Update the target network $\theta^- \leftarrow \theta$
    end if
    if $t \mod I_{AsyncUpdate} == 0$ or $s$ is terminal then
        Perform asynchronous update of $\theta$ using $d\theta$.
        Clear gradients $d\theta \leftarrow 0$.
    end if
until $T > T_{max}$

*Algorithm 1 of the paper "Asynchronous Methods for Deep Reinforcement Learning" by Volodymyr Mnih et al.*
Algorithm S2: Asynchronous n-step Q-learning - pseudocode for each actor-learner thread.

// Assume global shared parameter vector θ.
// Assume global shared target parameter vector θ⁻.
// Assume global shared counter T = 0.
Initialize thread step counter t ← 1

Parallel Advantage Actor Critic

An alternative to independent workers is to train in a synchronous and centralized way by having the workers to only generate episodes. Such approach was described in May 2017 by Clemente et al., who named their agent \textit{parallel advantage actor-critic} (PAAC).

Table 1 of the paper "Efficient Parallel Methods for Deep Reinforcement Learning" by Alfredo V. Clemente et al.

The authors use 8 workers, $n_e = 32$ parallel environments, 5-step returns, $\gamma = 0.99$, $\varepsilon = 0.1$, $\beta = 0.01$ and a learning rate of $\alpha = 0.0007 \cdot n_e = 0.0224$.

The $\text{arch}_{\text{nips}}$ is from A3C: 16 filters $8 \times 8$ stride 4, 32 filters $4 \times 4$ stride 2, a dense layer with 256 units. The $\text{arch}_{\text{nature}}$ is from DQN: 32 filters $8 \times 8$ stride 4, 64 filters $4 \times 4$ stride 2, 64 filters $3 \times 3$ stride 1 and 512-unit fully connected layer. All nonlinearities are ReLU.

Figure 4 of the paper “Efficient Parallel Methods for Deep Reinforcement Learning” by Alfredo V. Clemente et al.
Parallel Advantage Actor Critic

Figure 2 of the paper “Efficient Parallel Methods for Deep Reinforcement Learning” by Alfredo V. Clemente et al.
Continuous Action Space

Until now, the actions were discrete. However, many environments naturally accept actions from continuous space. We now consider actions which come from range \([a, b]\) for \(a, b \in \mathbb{R}\), or more generally from a Cartesian product of several such ranges:

\[
\prod_i [a_i, b_i].
\]

A simple way how to parametrize the action distribution is to choose them from the normal distribution. Given mean \(\mu\) and variance \(\sigma^2\), probability density function of \(\mathcal{N}(\mu, \sigma^2)\) is

\[
p(x) \overset{\text{def}}{=} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.
\]
Continuous Action Space in Gradient Methods

Utilizing continuous action spaces in gradient-based methods is straightforward. Instead of the softmax distribution we suitably parametrize the action value, usually using the normal distribution. Considering only one real-valued action, we therefore have

\[
\pi(a | s; \theta) \overset{\text{def}}{=} P \left( a \sim \mathcal{N}(\mu(s; \theta), \sigma(s; \theta)^2) \right),
\]

where \( \mu(s; \theta) \) and \( \sigma(s; \theta) \) are function approximation of mean and standard deviation of the action distribution.

The mean and standard deviation are usually computed from the shared representation, with

- the mean being computed as a regular regression (i.e., one output neuron without activation);
- the standard variance (which must be positive) being computed again as a regression, followed most commonly by either \( \exp \) or \( \text{softplus} \), where \( \text{softplus}(x) \overset{\text{def}}{=} \log(1 + e^x) \).
During training, we compute $\mu(s; \theta)$ and $\sigma(s; \theta)$ and then sample the action value (clipping it to $[a, b]$ if required). To compute the loss, we utilize the probability density function of the normal distribution (and usually also add the entropy penalty).

```python
mu = tf.layers.dense(hidden_layer, 1)[ :, 0]
sd = tf.layers.dense(hidden_layer, 1)[ :, 0]
sd = tf.exp(log_sd)  # or sd = tf.nn.softplus(sd)

normal_dist = tf.distributions.Normal(mu, sd)

# Loss computed as - log $\pi(a|s)$ - entropy_regularization
loss = - normal_dist.log_prob(self.actions) * self.returns -
     - args.entropy_regularization * normal_dist.entropy()
```
Continuous Action Space

When the action consists of several real values, i.e., action is a suitable subregion of $\mathbb{R}^n$ for $n > 1$, we can:

- either use multivariate Gaussian distribution;
- or factorize the probability into a product of univariate normal distributions.

Modeling the action distribution using a single normal distribution might be insufficient, in which case a mixture of normal distributions is usually used.

Sometimes, the continuous action space is used even for discrete output -- when modeling pixels intensities (256 values) or sound amplitude ($2^{16}$ values), instead of a softmax we use discretized mixture of distributions, usually logistic (a distribution with a sigmoid cdf). Then,

$$
\pi(a) = \sum_i p_i \left( \sigma\left(\frac{(a + 0.5 - \mu_i)}{\sigma_i}\right) - \sigma\left(\frac{(a - 0.5 - \mu_i)}{\sigma_i}\right) \right).
$$

However, such mixtures are usually used in generative modeling, not in reinforcement learning.
